The case of transcendence defect 0

• = • < =</p>

Categories of isocrystals

Throughout, let *k* be a field of characteristic p > 0. Let $X \subseteq Y$ be an open dense immersion of *k*-varieties. We consider the following categories:

(F-)Isoc[†](X, Y): (F-)isocrystals on X overconvergent within Y(F-)Isoc(X): =(F-)Isoc[†](X, X) (*convergent isocrystals*) (F-)Isoc[†](X): =(F-)Isoc[†](X, Y) with Y proper (*overconvergent isocrystals*)

For X smooth, elements of $\operatorname{Isoc}^{\dagger}(X, Y)$ are (locally) defined as vector bundles with integrable connection on a certain rigid analytic subspace of the (Raynaud) generic fibre of a *p*-adic formal lift of *Y* (a strict neighborhood of the tube of *X*), plus a convergence condition on the Taylor isomorphism.

These occur as analogues in rigid cohomology of smooth (lisse) ℓ -adic étale sheaves. The *unit-root* isocrystals correspond to *p*-adic representations of étale fundamental groups (Katz, Crew, Tsuzuki; see KSK, Swan conductors for *p*-adic differential modules II), but general isocrystals do not.

A rigidity property

We will use frequently the following rigidity property. (Can one drop smoothness using cohomological descent of Chiarellotto-Tsuzuki?)

Theorem (I, 5.2.1; II, 4.2.1; see also Caro, arXiv:0905.2210) Suppose X is smooth and $U \subseteq X$ is open dense. The restriction functors

$$(F-)$$
 Isoc[†] $(X, Y) \rightarrow (F-)$ Isoc[†] (U, Y)
 $F-$ Isoc[†] $(X, Y) \rightarrow F-$ Isoc (X)

are fully faithful.

Logarithmic isocrystals

By a *smooth pair*, we mean a pair (X, Z) with X smooth over k and Z a strict normal crossings divisor on X. Consider categories:

(*F*-)Isoc^{log}(*X*,*Z*): convergent log-(*F*-)isocrystals on (*X*,*Z*) (Shiho) (*F*-)Isoc^{nil}(*X*,*Z*): convergent log-(*F*-)isocrystals on (*X*,*Z*) with nilpotent residues along *Z* (see next slide)

Warning: it is *not known* how to construct a category of overconvergent $\log(F)$ isocrystals on (X, Z). We instead compute using local models, without assuming that these are independent of the choice of lifts. (This depends on rigidity.)

・ロト ・ 同ト ・ ヨト ・ ヨト ・ ヨ

Logarithmic isocrystals with nilpotent residues

Let (X,Z) be a smooth pair, let *D* be a component of *Z*, and put $Z' = Z \setminus D$. We may restrict $\mathscr{E} \in \operatorname{Isoc}^{\log}(X,Z)$ to (\mathscr{E}_D, N_D) where $\mathscr{E}_D \in \operatorname{Isoc}^{\log}(D, Z' \cap D)$ and $N_D \in \operatorname{Hom}(\mathscr{E}_D, \mathscr{E}_D)$ is horizontal. Call N_D the *residue* of \mathscr{E} along *D*. By definition, $\mathscr{E} \in \operatorname{Isoc}^{\operatorname{nil}}(X,Z)$ iff N_D is nilpotent for all *D*. This is automatic if \mathscr{E} carries a Frobenius, i.e.,

$$F$$
-Isoc^{log} $(X,Z) = F$ -Isoc^{nil} (X,Z)

(but not if only $\mathscr{E}|_U$ carries a Frobenius for some open dense $U \subseteq X$).

Theorem (I, 6.4.5)

The restriction functor

$$(F-)\operatorname{Isoc}^{\operatorname{nil}}(X,Z) \to (F-)\operatorname{Isoc}^{\dagger}(X \setminus Z,X)$$

is fully faithful. (This fails without requiring nilpotent residues.)

Alterations

An *alteration* $f : Y' \to Y$ is a proper, dominant, generically finite morphism. If *k* is perfect, we also assume *f* is generically étale.

Theorem (de Jong)

Let $X \subseteq Y$ be an open dense immersion of k-varieties. Then there exists an alteration $f: Y' \to Y$ such that $(Y', f^{-1}(Y \setminus X))$ is a smooth pair.

It is *not known* whether f can be taken to be finite over the regular locus of Y.

de Jong's theorem stands in for resolution of singularities over *k*. However, knowing resolution would not improve our main theorem *except* possibly by eliminating blowups outside the regular locus.

The semistable reduction theorem

Theorem (Semistable reduction; conjectured by Shiho)

Let $X \subseteq Y$ be an open immersion of k-varieties. For $f : Y' \to Y$ an alteration, put $X' = f^{-1}(X)$ and $Z' = Y' \setminus X'$. Then for any $\mathscr{E} \in F\operatorname{-Isoc}^{\dagger}(X,Y)$, we can choose f so that (Y',Z') is a smooth pair and $f^*\mathscr{E}$ is the restriction (uniquely) of an element of $F\operatorname{-Isoc}^{\operatorname{nil}}(Y',Z')$.

Semistable reduction is used by Caro and Tsuzuki to prove overholonomicity of overconvergent *F*-isocrystals, and by Shiho to construct generic higher direct images in relative rigid cohomology.

An analogue in characteristic 0: a higher-dimensional version of Turrittin's structure theorem for formal connections. See KSK, Good formal structures for flat meromorphic connections I, II.

(Notes for experts: I assume *discretely valued* coefficients, and I don't know anything about what happens without Frobenius structure.)

The case of transcendence defect 0

11/33

Local monodromy for isocrystals

Let (X, Z) be a smooth pair, put $U = X \setminus Z$, and let *D* be a component of *Z* with generic point η . For $\mathscr{E} \in (F-)$ Isoc[†](U, X), the *local monodromy module* of \mathscr{E} is the restriction \mathscr{E}_D of \mathscr{E} to

$$(F-)$$
 Isoc[†] (Spec Frac $(\widehat{\mathcal{O}_{X,\eta}})$, Spec $\widehat{\mathcal{O}_{X,\eta}}$).

given an appropriate definition of this category. (Concretely, these are finite free modules with connection over a ring of convergent Laurent series, i.e., a bounded Robba ring.)

Zariski-Nagata purity

We have analogues of (the easy case of) Zariski-Nagata purity.

Theorem (I, 5.2.1; extended by Shiho, arXiv:0806.4394)

Let $U \subseteq X \subseteq Y$ be open dense immersions with X smooth. Then the essential image of $\operatorname{Isoc}^{\dagger}(X,Y) \to \operatorname{Isoc}^{\dagger}(U,Y)$ consists of those \mathscr{E} for which \mathscr{E}_D extends to Isoc(Spec $\widehat{\mathcal{O}}_{X,n}$) for each codimension 1 component D of $X \setminus U$.

Theorem (I, 6.4.5; extended by Shiho, arXiv:0806.4394)

Let (X,Z) be a smooth pair, and put $U = X \setminus Z$. Then the essential image of $\operatorname{Isoc}^{\operatorname{nil}}(X,Z) \to \operatorname{Isoc}^{\dagger}(U,X)$ consists of those & for which \mathcal{E}_D extends to Isoc^{nil}(Spec $\widehat{\mathcal{O}_{X,\eta}}, \eta$) for each component D of Z.

In these cases, I'll say \mathcal{E}_D is extendable (resp. log-extendable).

Some sample corollaries

Theorem (I, 5.3.1)

Let $U \subseteq X \subseteq Y$ be open dense immersions with X smooth. For $\mathscr{E} \in \operatorname{Isoc}^{\dagger}(X, Y)$, any subobject of \mathscr{E} in $\operatorname{Isoc}^{\dagger}(U, Y)$ lifts to a subobject of \mathscr{E} in $\operatorname{Isoc}^{\dagger}(X, Y)$.

This follows because the property that \mathscr{E}_D is constant passes to all subobjects. (Beware: the analogous statement for the restriction $\operatorname{Isoc}^{\dagger}(X) \to \operatorname{Isoc}(X)$ is false! Consider, e.g., a unit-root subcrystal.)

Theorem (I, 5.3.7)

Let $U \subseteq X \subseteq Y$ be open dense immersions with X smooth. Then

$$\operatorname{Isoc}(X) \times_{\operatorname{Isoc}^{\dagger}(U,X)} \operatorname{Isoc}^{\dagger}(U,Y) = \operatorname{Isoc}^{\dagger}(X,Y).$$

(With Frobenius structures, one can multiply over F-Isoc(U).)

Local monodromy and semistable reduction

Valuation-theoretic localization

The case of transcendence defect 0

(3)

Krull valuations

Let *X* be an irreducible *k*-variety. A *Krull valuation* on k(X) over *k* is a function $v : k(X) \to \Gamma \cup \{\infty\}$ for some totally ordered group Γ , such that:

•
$$v(x) = \infty$$
 iff $x = 0$, and $v(x) = 0$ for all $x \in k^{\times}$;

Define

$$\begin{split} &\Gamma_{v} = v(k(X)^{\times}) \qquad (value\ group) \\ &\mathfrak{o}_{v} = \{x \in k(X) : v(x) \geq 0\} \qquad (valuation\ ring) \\ &\mathfrak{m}_{v} = \{x \in k(X) : v(x) > 0\} \qquad (maximal\ ideal) \\ &\kappa_{v} = \mathfrak{o}_{v}/\mathfrak{m}_{v} \qquad (residue\ field) \end{split}$$

The *center* of *v* on *X* is $\{x \in X : \mathfrak{o}_{X,x} \subseteq \mathfrak{o}_v\}$. If nonempty (e.g., if *X* is proper), it is closed and irreducible of dimension $\leq \operatorname{trdeg}(\kappa_v/k)$, and *v* is *centered on X*.

Divisorial valuations and semistable reduction

We say *v* is *divisorial* if *v* measures order of vanishing along some divisor on some variety birational to *X*. In particular, $\Gamma_v \cong \mathbb{Z}$.

Let $X \subseteq Y$ be an open immersion of irreducible *k*-varieties. For $\mathscr{E} \in \operatorname{Isoc}^{\dagger}(X, Y)$, we get a local monodromy module \mathscr{E}_{v} for each divisorial valuation *v* on k(X) centered on *Y*.

Theorem (approximately II, 3.4.4)

 \mathscr{E} admits semistable reduction if and only if there exists a finite cover $X' \to X$ with X' irreducible, such that for each divisorial valuation v on k(X) centered on Y, for some extension w of v to k(X'), \mathscr{E}_w is log-extendable.

One can achieve this for a *single v* using the theorem of André-Mebkhout-KSK (Crew's conjecture). However, that plus Zariski-Nagata purity do not suffice: we cannot control singularities of X'.

Riemann-Zariski spaces

Let $S_{k(X)/k}$ be the set of equivalence classes of Krull valuations on k(X) over k. (Here $v \sim v'$ iff $\mathfrak{o}_v = \mathfrak{o}_{v'}$.) This carries the *Zariski-Hausdorff topology*, specified by the basis of opens given by

$$\{v \in S_{k(X)/k} : v(f_1), \dots, v(f_m) \ge 0; v(g_1), \dots, v(g_n) > 0\}$$

for any $f_1, ..., f_m, g_1, ..., g_n \in k(X)$.

Theorem (Zariski)

The topological space $S_{k(X)/k}$ is compact.

Local semistable reduction

Let $X \subseteq Y$ be an open immersion of irreducible *k*-varieties. For $f : Y' \to Y$ an alteration, put $X' = f^{-1}(X)$ and $Z' = Y' \setminus X'$.

For $\mathscr{E} \in F$ -Isoc[†](X, Y) and $v \in S_{k(X)/k}$ centered on Y, \mathscr{E} admits *local* semistable reduction at v if there exists an alteration $f : Y' \to Y$ with Y'irreducible and an open $U \subseteq Y'$ such that $(U, U \cap Z')$ is a smooth pair, some extension of v to k(Y') is centered on U, and $f^*\mathscr{E}$ lifts from F-Isoc[†] $(X' \cap U, U)$ to F-Isoc^{nil} $(U, U \cap Z')$.

Using Zariski's compactness theorem, we obtain the following.

Theorem (II, 3.3.4, 3.4.5; IV, 2.4.2)

Suppose that \mathscr{E} admits local semistable reduction at all $v \in S_{k(X)/k}$ centered on Y, Then \mathscr{E} admits semistable reduction.

Note: we need all v, not just divisorial valuations, so \mathcal{E}_v may not make sense.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

Abhyankar's inequality

The *height* (*real rank*) of v is the minimum m such that Γ_v embeds into the lexicographic product \mathbb{R}^m .

The *rational rank* of *v* is dim_{\mathbb{Q}}($\Gamma_v \otimes_{\mathbb{Z}} \mathbb{Q}$). Note that height(*v*) \leq ratrank(*v*).

The *transcendence defect* of v is

 $\operatorname{trdefect}(v) = \dim(X) - \operatorname{ratrank}(v) - \operatorname{trdeg}(\kappa_v/k).$

Theorem (Abhyankar)

For any $v \in S_{k(X)/k}$, trdefect(v) ≥ 0 . Moreover, if trdefect(v) = 0, then $\Gamma_{\nu} \cong \mathbb{Z}^{\operatorname{ratrank}(\nu)}$ and κ_{ν} is finitely generated over k.

A valuation v with trdefect(v) = 0 is called an *Abhyankar valuation*. These are dense in $S_{k(X)/k}$, since they include divisorial valuations.

Reductions

Theorem (II, 3.2.6)

To prove (local) semistable reduction for a given isocrystal, it suffices to do so after base change from k to k^{alg} .

Theorem (II, 4.2.4, 4.3.4)

To prove local semistable reduction over an algebraically closed field k, it suffices to do so for all valuations v with height(v) = 1 and $\kappa_v = k$.

Contents

- Statement of the theorem
- Local monodromy and semistable reduction

- The case of transcendence defect 0

Local uniformization for Abhyankar valuations

Assume from now on that $k = k^{\text{alg}}$. Let $X \subseteq Y$ be an open dense immersion of irreducible *k*-varieties. Let *v* be a valuation on k(X) over *k* centered on *Y* with trdefect(v) = 0 and $\kappa_v = k$.

Theorem (Kuhlmann, Knaf)

There is a blowup Y' of Y and local coordinates t_1, \ldots, t_n on Y' at the center of v, such that

$$\alpha_1 = v(t_1), \ldots, \alpha_n = v(t_n)$$

are linearly independent over \mathbb{Q} and generate Γ_v as a \mathbb{Z} -module.

For $\beta = (\beta_1, \dots, \beta_n) \in \mathbb{R}^n$, let v_β denote the $(\beta_1, \dots, \beta_n)$ -Gauss valuation in terms of t_1, \dots, t_n . Then the completion $k(X)_v$ is isomorphic to the v_α -completion of $k[t_1^{\pm}, \dots, t_n^{\pm}]$.

Differential ramification breaks

Take $\mathscr{E} \in \text{Isoc}^{\dagger}(X, Y)$ of rank *d*. Fix $\beta = (\beta_1, \dots, \beta_n) \in \mathbb{R}^n$. We may realize \mathscr{E} as a ∇ -module on a subspace of the rigid or nonarchimedean analytic (t_1, \dots, t_n) -affine space including (for some $\varepsilon \in (0, 1)$)

$$\{(t_1,\ldots,t_n): (|t_1|,\ldots,|t_n|) = (\rho^{\beta_1},\ldots,\rho^{\beta_n}) \text{ for some } \rho \in (\varepsilon,1)\}.$$

Then there exist $b_1(\mathscr{E},\beta) \geq \cdots \geq b_d(\mathscr{E},\beta) \geq 0$ such that the intrinsic subsidiary generic radii of convergence at $(|t_1|,\ldots,|t_n|) = (\rho^{\beta_1},\ldots,\rho^{\beta_n})$ are equal to $\rho^{b_1(\mathscr{E},\beta)},\ldots,\rho^{b_d(\mathscr{E},\beta)}$. These are the *differential ramification breaks* of \mathscr{E} along v_β (at least if $\beta \in \mathbb{Q}^n$).

In the one-dimensional case, these are ordinary ramification breaks of the local monodromy representation (Crew, Matsuda, Tsuzuki). For more discussion, see: KSK, Swan conductors for *p*-adic differential modules, I, II.

・ロト・(理)・・ヨト・ヨト ヨー のへの

Variation of differential Swan conductors

For $\beta = (\beta_1, \dots, \beta_n) \in \mathbb{Q}^n$, the differential ramification breaks satisfy

$$d!b_i(\mathscr{E},\beta) \in \mathbb{Z}\beta_1 + \cdots + \mathbb{Z}\beta_d \qquad (i=1,\ldots,d).$$

Moreover, $b_1(\mathcal{E}, \beta) = 0$ if and only if \mathcal{E}_{ν_β} becomes unipotent after pulling back along a cover tamely ramified along $t_1 \cdots t_n = 0$ (III, 5.2.5). Define

$$B_i(\mathscr{E},\beta) = b_1(\mathscr{E},\beta) + \cdots + b_i(\mathscr{E},\beta).$$

Theorem (III, 2.4.2, 4.4.7 for i = 1; KSK, Xiao in general)

The functions $d!B_i(\mathcal{E},\beta)$ and $B_d(\mathcal{E},\beta)$ are convex and piecewise integral affine (integral polyhedral) on $\beta \in [0,+\infty)^n$.

Two approaches to local semistable reduction

Original approach (III, 6.3.1): use an analogue of the *p*-adic local monodromy theorem (KSK, The *p*-adic local monodromy theorem for fake annuli) to reach a situation (after suitable alteration) where $b_1(\mathscr{E}, \alpha) = 0$. Since $d!b_1(\mathscr{E}, \beta) = d!B_1(\mathscr{E}, \beta)$ is integral polyhedral, this forces $b_1(\mathscr{E}, \beta)$ to vanish identically in a neighborhood of α .

Alternate approach (sketched in IV, appendix): imitate Mebkhout's proof of the monodromy theorem, replacing Christol-Mebkhout decomposition theory with its higher-dimensional analogue (KSK-Xiao).

Both of these depend crucially on being able to describe v in local coordinates. For the case trdefect(v) > 0, a new idea is needed.

Setup

Again, assume that *v* is a valuation on k(X) centered on *v* with $\kappa_v = k$, but now suppose trdefect(*v*) = *m* > 0. Assume local semistable reduction for all *w* with trdefect(*w*) < *m*.

Unfortunately, ν does not admit a sufficiently convenient description in local coordinates to permit an analogue of our argument in the transcendence defect 0 case. This is in part because Γ_{ν} need not be finitely generated over \mathbb{Z} .

Instead, argue by induction on transcendence defect. Related arguments:

- Temkin, Inseparable local uniformization, arXiv:0804.1554.
- KSK, Good formal structures for formal meromorphic connections II.
- Possibly an application to multiplier ideals, following Boucksom, Favre, Jonsson.

イロト 不得 とくき とくき とうき

Induction on transcendence defect via fibrations

Choose a fibration $\pi : Y \to Y^0$ in curves such that $k(Y^0)$ contains a \mathbb{Q} -basis of $\Gamma_v \otimes_{\mathbb{Z}} \mathbb{Q}$. Then the restriction v^0 of v to $k(Y^0)$ satisfies

$$trdefect(v^0) = trdefect(v) - 1 = m - 1.$$

Let $z \in Y$ be the center of v, and put $z^0 = \pi(z)$. Let $x \in k(Y)$ restrict to $\pi^{-1}(z^0)$ giving a local parameter at z.

We allow the following operations on the geometric data (IV, 5.1.6–9).

- (i) Change base: replace Y^0 by an alteration or a finite radicial cover.
- (ii) Blow up: adjoin (x-g)/h for $g,h \in k(Y^0)$ with $v(x-g) > v(h) \ge 0$.
- (iii) Make a tame cover: adjoin $x^{1/m}$ for some positive integer *m* coprime to *p*.
- (iv) Make a *special Artin-Schreier cover*: adjoin *uf* such that $u^p u = y/f^p$ with $f \in k(Y^0)$ and $y \in \lambda x + \mathfrak{m}_{X,z}$ for some $\lambda \in k^{\times}$.

A path in valuation space

We identify *v* with a multiplicative seminorm on $k(Y^0)_{v^0}[x]$ bounded by the 1-Gauss norm, corresponding to a point of type 1 (classical) or 4 (spherical) in the Berkovich open unit disc \mathbb{D} over $k(Y^0)_{v^0}$.

Using pointwise comparison on $k(Y^0)_{v^0}[x]$ as a partial ordering, \mathbb{D} forms a tree in which *v* is a leaf. Let \mathscr{P} be the branch ending at *v*. Each $w \in \mathscr{P} \setminus \{v\}$ "is" a valuation on k(Y) with transcendence defect m - 1, so \mathscr{E} admits local semistable reduction at *w*.

Note that we can shorten \mathscr{P} (on the side away from *v*) using the blowup operation (ii) on the geometric data.

Local monodromy representations

For each valuation *w* at which local semistable reduction is known, one obtains a (semisimplified) local monodromy representation τ_w of the inertia subgroup I_w of $\pi_1^{\text{et}}(k(Y), *)$; it is a linear representation having *finite image* (IV, 2.5.2). If τ_w is trivial and (Y, Z) is a smooth pair, then \mathscr{E} is log-extendable on some open dense subscheme of *Y* on which *w* is centered.

This applies to $w \in \mathscr{P} \setminus \{v\}$. The result is reflected in the tensor category of \mathscr{E} restricted to some annulus centered at *v*. In particular, if this category is trivial, then we can kill the local monodromy representation at *w* using a base change. We then get local semistable reduction at *v* via Zariski-Nagata purity.

Strategy: reduce to this case by showing that the tensor category structures for different *w*'s are "coherent", finding a subobject corresponding to a special Artin-Schreier character, trivializing this character, and repeating. Only finitely many iterations possible, after which we win. (Compare Mebkhout's proof of Crew's conjecture.)

Numerical invariants

Identify \mathscr{P} with an interval $(0, s_0]$ by identifying w with $s = -\log \operatorname{radius}(w)$. (The *radius* of $w \in \mathscr{P}$ is the infimum of the radii of discs containing w.)

We define certain numerical invariants $b_1(\mathscr{E}, s) \ge \cdots \ge b_d(\mathscr{E}, s) \ge s$ for $w \in \mathscr{P}$, akin to the differential ramification breaks (IV, 3.1.3, 5.2.3). Put $B_i(\mathscr{E}, s) = b_1(\mathscr{E}, s) + \cdots + b_i(\mathscr{E}, s)$.

Theorem (IV, 3.1.4, 4.7.5)

The $d!B_i(\mathcal{E}, s)$ are convex and piecewise affine with integral slopes; the slopes are nonpositive as long as $b_i(\mathcal{E}, s) > s$. Moreover, in a neighborhood of v, each $b_i(\mathcal{E}, s)$ is either constant or identically s.

This uses quantitative Christol-Mebkhout theory (KSK, *p*-adic differential equations) plus some difficult calculations. (Reduces to: for $Q \in k(Y)[T]$, the Newton polygon of Q at a point of \mathscr{P} becomes constant near *v*.)

Endgame

Using what we have so far, we can force the situation where \mathscr{E} and $\mathscr{E}^{\vee} \otimes \mathscr{E}$ decompose the same way over any annulus centered at *v*. Unless we are in the good case, we can force one of these to have a rank 1 subquotient \mathscr{F} whose p^n -th tensor power is trivial for some n > 0. (Reduces to: for τ a nontrivial linear representation of a finite *p*-group whose coefficient field is algebraically closed of characteristic 0, either τ or $\tau^{\vee} \otimes \tau$ has a nontrivial rank 1 subrepresentation.)

Using some careful analysis of Dwork isocrystals (and again quantitative Christol-Mebkhout), we show that $\mathscr{F}^{\otimes p^{n-1}}$ is trivialized by a *special* Artin-Schreier cover (II, 5.6.3).

This can only happen finitely many times, after which we win.
